SUMMAR Y

The upper limit on the stoichiometric equilibrium constant for the tetrachloroaluminate dissociation reaction, $2RA1Cl_4 = RA1_2Cl_7 + RCl$, was investigated in the room temperature ionic liquid aluminum chloride-1-methyl-3-ethylimidazolium chloride by means of a potentiometric titration procedure. The values obtained at 40, 50, and $60^{\circ}C$ were $5.1 \pm 1.4 \times 10^{-17}$, $1.8 \pm 1.6 \times 10^{-16}$, and $3.8 \pm 1.1 \times 10^{-16}$, respectively. A curve fitting procedure for locating the equivalence point in these titrations is also described.

PREFACE

This report describes work performed under FJSRL Work Unit 2303-F2-10, Organic and Inorganic Electrochemical Measurements. Portions of the experimental part of this study were carried out in the Department of Chemistry at the University of Mississippi. Capt. Hussey is a reservist assigned to the Air Force Office of Scientific Research and attached to FJSRL. Dr. Scheffler is a National Research Council research associate at FJSRL. Dr. Wilkes and Lt. Col. Fannin are permanent staff members at FJSRL.

- Table A-I. Results for calculation of initial melt compositions.
- Table B-I. Example of a fitting cycle for determination of \underline{K}' from Eq. (B-1).

I. Introduction

Aluminum chloride can be combined with certain organic salts to produce ionic liquids that are molten at room temperature. Familiar examples of such liquids are mixtures of aluminum chloride with N-(n-butyl)pyridinium chloride (BPC) (1,2). However, a new class of room temperature chloroaluminate melts, based on dialkylimidazolium chloride salts, was described recently (3). Mixtures of aluminum chloride, with one of these salts, 1-methyl-3-ethylimidazolium chloride (MEIC), exhibit both a wider electrochemical window and higher electrical conductivity, and are liquid over a larger composition range than corresponding systems based on N-alkylpyridinium halides.

The Lewis acid-base properties of room temperature chloroaluminate melts are governed essentially by the single equilibrium (3-5):

$$^{\circ} 2RA1C1_{4} \stackrel{\underline{K}}{=} RA1_{2}C1_{7} + RC1 \tag{1}$$

Melts that contain a molar excess of aluminum chloride to organic salt are Lewis acidic by virtue of the coordinately unsaturated Al₂Cl₇⁻ ion.

Conversely, mixtures that contain an excess of the organic salt relative to aluminum chloride are Lewis basic due to uncomplexed chloride ion.

The acid-base properties of ionic liquids based on AlCl₃-BPC have been investigated and estimates of the upper limit on the equilibrium constant for Eq. (1) are available for this liquid (4,5). Karpinski and Osteryoung (6) have demonstrated that it is not possible to measure an exact value of K for Eq. (1) if aluminum electrodes are used for the measurements. This is because an aluminum electrode immersed in basic melt experiences a mixed potential that is

less negative than the true potential of the A1(III)/A1 redox couple. Two sources of this mixed potential have been advanced (6): corrosion of aluminum by the organic cation (this phenomenon is well-known in the A1Cl₃-BPC melt (7)) and corrosion of aluminum by adventitious hydrogen ion. In place of aluminum electrodes, Karpinski and Osteryoung suggested the use of the Cl₂/Cl⁻ couple for determining chloride ion activity. Unfortunately, it has been found that Cl₂ reacts with the organic cation in A1Cl₃-MEIC melts, eventually chlorinating all available sites on the cation (8). Thus, the chlorine electrode is not the catholicon for these measurements, either.

This technical report describes a study of the acid-base properties of the $AlCl_3$ -MEIC melt. Potentiometric measurements were undertaken at aluminum electrodes in order to estimate the upper limit on \underline{K} for Eq. (1).

II. Experimental

garandiyosyaasid boobbood kaararara bobboob - borbaar ahaasasid kararaka bararara - babboob - barababaa B

Instrumentation. Experiments were conducted in a dry, oxygen-free nitrogen atmosphere inside a Kewaunee Scientific Engineering Corp. dry box system equipped with a Model 2C2500 30-cfm inert-gas purifier. The procedure for estimating the moisture and oxygen content of this dry box using a 25 W light bulb has been described (9). Instrumentation used to perform cyclic voltammetry and to make potentiometric measurements was identical to that used previously (10). Pulse polarographic experiments were undertaken with a PARC Model 174 polarographic analyzer.

AMERICAN TELESCOPIA TO SOCIAL TO SECURIS TO SOCIAL PROPERTY OF SOCIAL

Cells and Electrodes. The cell and furnace used were described previously

(9). Aluminum electrodes were fashioned from 1.0-mm diameter aluminum wire

(Alfa Products, m5N purity). These electrodes were immersed briefly in a

aqueous solution that was 5% (v/v) in HF and 15% (v/v) in HNO₃, rinsed with distilled water, and dried under vacuum before use.

Chemicals. Aluminum chloride (Fluks, A.G.) was triply sublimed under vacuum inside the dry box. The synthesis and purification of 1-methy1-3-ethylimidazolium chloride was identical to that described by Wilkes et al.

This salt was carefully purified using airless techniques; it as recrystallized three times from mixtures of acetonitrile and ethyl acetate. The oxide content of the AlCl3-MEIC melt was determined with TiCl4 using a pulse polarographic method (11). Melts that contained more than 5 ppm oxide were discarded.

When A1Cl₃ is mixed with MEIC, a violent exothermic reaction takes place which results in sublimation loss of A1Cl₃ and decomposition of small amounts of MEIC. Consequently, it is very difficult to prepare a large amount of melt of an accurately known composition by combining preweighted quantities of the components. Therefore, it was necessary to determine the initial melt composition directly from titration data. Two procedures were used. The first was based on an approximation of Grans method and is similar to that described by Schoebrechts and Gilbert (5). The second method is described in Appendix A. For brevity, A1Cl₃-MEIC melt compositions specified in this paper are given in terms of the formal more fraction, N, or mole percent, mole/o, of A1Cl₃ in the mixture.

III. Results and Discussion

Stability of aluminum in basic AlCl3-MEIC melt. As previously noted, the instability of aluminum in basic melt can complicate the study of chloroaluminate equilibria. For example, aluminum behaves as a reducing agent

toward the 1-(n-buty1)pyridinium cation in basic A1C1₂-BPC melt. The addition of aluminum to this melt produces the highly colored 4,4'-dibutyl-1,1'bipyridinium monocation radical (9). MNDO calculations suggest that the 1methy1-3-ethylimidazolium cation is substantially more difficult to reduce than the $1-(\underline{n}-\text{buty1})$ pyridinium cation (3). In fact, the latter species can be electrochemically reduced in basic AlCl3-MEIC melt prior to the negative limit of the solvent. Figure 1 shows a cyclic voltammogram for the reduction of $1-(\underline{n}$ buty1)pyridinium cation at a glassy carbon electrode in basic A1Cl3-MEIC. The reduction peak potential for this solute, -1.43 V versus aluminum in 66.7 mole/o A1Cl3-MEIC, is considerably positive of the negative limit of the 44.4 mole/o A1C13-MEIC melt at -2.20 V. Thus, aluminum should be more stable thermodynamically with regard to oxidation in basic AlCl3-MEIC relative to basic A1Cl3-BPC. Immersion of small pieces of aluminum foil in basic A1Cl3-MEIC for several weeks did not result in discernable changes in the aluminum or the melt, while similar experiments with basic AlCl₃-BPC indicated reduction of the 1-(\underline{n} butyl)pyridinium cation within a few days. However, it was not possible to electrochemically deposit aluminum at aluminum or glassy carbon electrodes in basic A1Cl3-MEIC melt, prolonged electrolysis produced an orange-colored solution in the cathode compartment of the cell.

Potentiometric titration experiments. The concentration cell with transference shown below was used to study chlorosluminate equilibria in AlCl3-MEIC melt:

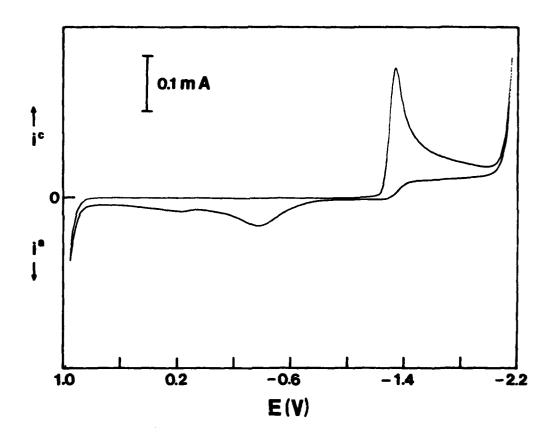

Figure 1. Cyclic voltammogram for the reduction of the 1-(n-butyl)pyridinium cation at a glassy electrode in 44 mole/o AlCl3-MEIC melt at 40.0°C. Sweep rate was 50 mV/sec.

Both compartments of this cell were filled with melt that was ca. 60 mole/o in AlCl₃ prior to the start of an experiment. Weighed portions of MEIC were added to compartment 2 of the cell during an experiment and the potential of the cell was recorded after dissolution of the MEIC. The aluminum electrodes were carefully wiped with abrasive tissue (Kimwipes) before each data point was recorded. The melt composition in the left-hand cell compartment was kept constant. Figure 2 shows representative titration curves obtained at 40.0, 50.0, and 60.0°C, using this cell. Several experiments were conducted at each temperature. Cell potentials were stable and reproducible throughout each titration experiment.

Analysis of chlorosluminate concentration cells. One and King (12) reported that the potential of a chlorosluminate concentration cell with transference, similar to that shown in Eq. (2), is given formally by the expression

$$\underline{FE} = \int_{1}^{2} 1/3 d\mu_{A1C1_{3}}^{2} - \frac{t_{A1}}{3} d\mu_{A1C1_{3}}^{2} - t_{R} d\mu_{RC1}$$
 (3)

In Eq. (3), RC1 represents MEIC, and $t_{\rm Al}$ and $t_{\rm R}$ are the formal transport numbers of the aluminum ion and the melt cation, respectively. Hussey and Gye (13) have measured transport numbers in the AlCl₃-MEIC melt. The internal transport number of the organic cation relative to chloride is 1.00 in this melt. In this event Eq. (3) simplifies to

$$\underline{FE} = \int_{1}^{2} 1/3 d\mu_{A1C1_{3}} - d\mu_{RC1}$$
 (4)

Equation (4) may also be written in terms of the activities of the major chloroaluminste species in basic melt

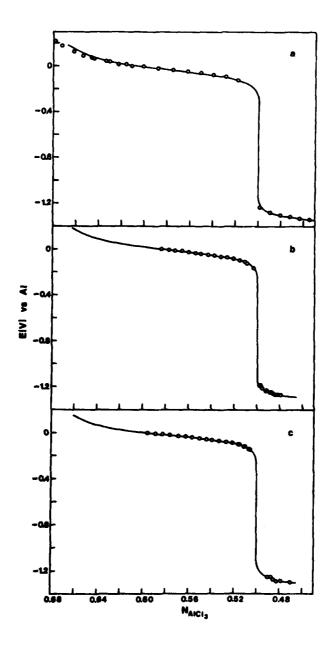

Figure 2. Potentiometric titration curves for the A1Cl₃-MEIC system; a) 60.0°C, b) 50.0°C, and c) 40.0°C. Solid lines were calculated from the estimated equilibrium constants for Eq. (1) that were determined from the experimental data in each figure.

SECTION OF SECRETARION OF SECTION OF SECTION

$$\underline{\underline{E}} = \frac{\underline{RT}}{3F} \int_{1}^{2} dl \, \underline{n_{RA1C1}}_{4} - 4 dl \, \underline{n_{RC1}}$$
 (5)

or in acidic melt

$$\underline{\mathbf{E}} = \frac{RT}{3F} \int_{1}^{2} 4d1 \, n_{RA12} \, C_{17} - 7d1 \, n_{RA1C14} \tag{6}$$

Autosovolysis equilibrium constant. - The stoichiometric equilibrium constant for the reaction depicted in Eq. (1) is defined as

$$\underline{\mathbf{K}'} = \frac{(\underline{\mathbf{X}}_{\mathbf{RC1}})(\underline{\mathbf{X}}_{\mathbf{RA1}_2}\underline{\mathbf{C1}_7})}{(\underline{\mathbf{X}}_{\mathbf{RA1}_2}\underline{\mathbf{C1}_4})^2} \tag{7}$$

where $\underline{\mathbf{X}}_{RC1}$, $\underline{\mathbf{X}}_{RA1C1}$, and $\underline{\mathbf{X}}_{RA1}$ represent the mole fractions of RC1, RA1C1₄, and and RA1₂C1₇. Values of $\underline{\mathbf{K}}$ ' for the A1C1₃-MEIC system were obtained by curve fitting data in the vicinity of the 50 mole/o composition to the equation

$$\underline{\underline{E}} = \frac{4\underline{R}\underline{T}}{3\underline{F}} \ln \frac{\underline{\underline{K}}'(\underline{\underline{I}}_{RA1}C1_{4})^{2}_{A}}{(\underline{\underline{I}}_{RC1})_{B}(\underline{\underline{I}}_{RA1}C1_{4})^{A}_{A}} + \frac{\underline{R}\underline{T}}{3\underline{F}} \ln \frac{(\underline{\underline{I}}_{RA1}C1_{4})_{B}}{(\underline{\underline{I}}_{RA1}C1_{4})_{A}}$$
(8a)

where A and B denote acidic and basic compartments, and $\underline{E} = \underline{E}_B - \underline{E}_A$. The details of this procedure are given in Appendix B. Average values of the upper limit of \underline{E}' , resulting from several experiments, are listed in Table I and are compared with other chloroaluminate systems. The approximate distribution of ionic species in AlCl₃-MEIC melt, calculated by using the \underline{E}' value at 40° C given in Table I, is shown in Figure 3. The equilibrium constants for Eq. (1) are several orders of magnitude smaller in AlCl₃-MEIC than those determined for the AlCl₃-BPC system. This suggests that the value of \underline{E}' obtained in the present study is probably much closer to the true value of \underline{E}' than estimates propounded by other workers (4,5). In fact, Karpinski and Osteryoung (6) predict that the

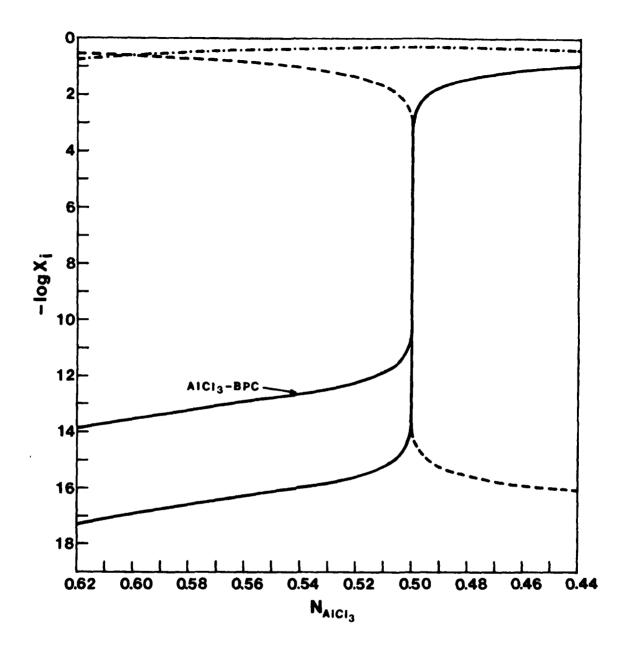

Figure 3. Distribution of species in the $AlCl_3$ -MEIC melt at 40.0° C, -, log \underline{X}_{RC1} ; -', $log \underline{X}_{RA1Cl_4}$; - -, $log \underline{X}_{RA1_2Cl_7}$ The upper limit on log \underline{X}_{RC1} , attainable in the $AlCl_3$ -BPC melt, is shown for comparison. Values of $log \underline{X}_{RC1}$ for the $AlCl_3$ -BPC system were calculated from the estimates of \underline{X}' given in reference 5.

exercist exercised discovers. Despective discovers and despetable and

actual value of \underline{K}' for both the AlCl₃-BPC and AlCl₃-MEIC melts may lie in the interval from 10^{-19} to 10^{-15} . Nevertheless, the estimates of \underline{K}' reported herein should be considered to be the upper limit on \underline{K}' due to the various side reactions which complicate the aluminum electrode reaction in basic melt.

IV. Conclusion

The solid lines that appear in Fig. 1 were calculated by using estimates of $\underline{\mathbf{E}}'$ that were determined directly from the experimental data shown in each figure. These lines were calculated by using the integrated forms of Eqs. (5) and (6). It is interesting to note that in every case (Fig. 1) these calculated lines represent the experimental data precisely, except in very acid melt where the AlCl₃ content exceeds <u>ca.</u> 63 mole/o. It should be noted that recent ²⁷Al NMR studies suggest the presence of Al₃Cl₁₀ in very acid AlCl₃-MEIC melt (17). Therefore, it may be necessary to consider other equilibria in addition to Eq. (1) in very acidic melt.

VI. Appendix A:

The initial composition of the melt in the cell (Eq. (2)) and each new composition arising in compartment 2 of the cell after the addition of a known amount of MEIC were determined by the curve fitting technique described below.

When RA1₂Cl₇ and RA1Cl₄ in the equation

$$\underline{E} = \frac{4\underline{R}\underline{T}}{3\underline{F}} \ln \frac{(\underline{X}_{RA1_2}C1_7)_2}{(\underline{X}_{RA1_2}C1_7)_1} + \frac{7\underline{R}\underline{T}}{3\underline{F}} \ln \frac{(\underline{X}_{RA1}C1_4)_1}{(\underline{X}_{RA1}C1_4)_2}$$
(A-1)

are represented in terms of the apparent mole fractions of A1Cl $_3$ in compartments 1 and 2 of the cell \underline{N}_1 and \underline{N}_2 , respectively, Eq. (A-2) results:

$$\underline{\underline{B}} = \frac{4\underline{R}\underline{T}}{3\underline{F}} \ln \left[\frac{2\underline{N}_2 - 1}{2\underline{N}_1 - 1} \right] \left[\frac{1 - \underline{N}_2}{1 - \underline{N}_1} \right] + \frac{7\underline{R}\underline{T}}{3\underline{F}} \ln \left[\frac{2 - 3\underline{N}_1}{2 - 3\underline{N}_2} \right] \left[\frac{1 - \underline{N}_2}{1 - \underline{N}_1} \right]$$
(A-2)

Furthermore, \underline{N}_1 and \underline{N}_2 can be expressed in terms of the initial weight of melt, $\underline{\underline{W}}_m$, and the initial weight of salt, $\underline{\underline{W}}_8^i$, and the cumulative weight of salt added at each point, $\underline{\underline{W}}_8^i$, in compartment 2, according to Eqs. (A-3) and (A-4):

$$\underline{N}_{1} = \frac{\underline{\underline{Y}}_{m} - \underline{\underline{Y}}_{s}^{i}}{\underline{\underline{Y}}_{m} - \underline{\underline{Y}}_{s}^{i}(1 - \underline{\underline{R}})}$$
(A-3)

$$\underline{N}_2 = \frac{\underline{\underline{W}}_m - \underline{\underline{W}}_s^{\underline{i}}}{\underline{\underline{W}}_m - \underline{\underline{W}}_s^{\underline{i}}(1-\underline{\underline{R}}) + \underline{\underline{W}}_s\underline{\underline{R}}}$$
 (A-4)

 \underline{R} represents the ratio of the formula weight of $AlCl_3$ to that of the organic salt. Substitution of Eqs. (A-3) and (A-4) into (A-2) results in a complex equation that can be computer fitted to measurements of \underline{E} at each \underline{W}_8 in acidic melt. This equation can be used to calculate \underline{W}_8^1 if \underline{W}_{m} is known.

A Fortran IV computer program was written for this purpose. This program uses a Taylor series linearized least-squares routine to obtain the value of \mathbb{Y}^1_S that minimized the error between the experimental potential and the calculated potential. Estimates of the melt composition obtained with this procedure are at least as good as those obtained by using Grans method (5), of, Table A-I. One significant advantage of the procedure described herein over the other method (5) is that it is not necessary to collect a large amount of titration data immediately prior to the equivalence point. This can result in considerable experimental convenience when a good estimate of the initial melt composition is not available.

CONTRACTOR OF STATE O

Table A-I. Results for calculation of initial melt compositions.

t (°C)		elt composition e/o AlCl ₃)	% relative difference
	this work	Grans method (5)	
0.0	60.73	60.10	1.0
	60.34	59.72	1.0
	59.54	59.45	0.2
0.0	58.83	58.59	0.4
	58.43	58.27	0.3

	59.08	59.09	0.0
	59.82	60.16	-0.6

VII. Appendix B:

The values of \underline{K}' that appear in Table I were calculated from potentiometric titration data in the 50.0 \pm 4.0 mole/o composition region using this modified version of Eq. (8):

$$\underline{\underline{E}}_{\underline{i}} - \underline{\underline{E}}_{\underline{j}} = \frac{4\underline{R}\underline{T}}{3\underline{F}} \operatorname{In} \frac{(2-3\underline{N}_{\underline{i}})^{2}(1-\underline{N}_{\underline{j}})\underline{\underline{K}'}}{(1-\underline{N}_{\underline{i}})(2\underline{N}_{\underline{i}}-1)(1-2\underline{N}_{\underline{j}})} + \frac{\underline{R}\underline{T}}{3\underline{F}} \operatorname{In} \frac{\underline{N}_{\underline{j}}(1-\underline{N}_{\underline{i}})}{(1-\underline{N}_{\underline{j}})(2-3\underline{N}_{\underline{i}})}$$
(B-1)

Data, consisting of the potential differences between an acidic reference point, \underline{N}_i , and a series of basic data points, \underline{N}_j , were fitted to Eq. (B-1) so as to minimize the sum of the errors between calculated and experimental values of \underline{E}_i — \underline{E}_j . This procedure was repeated successively for each value of \underline{N}_i that was in the appropriate composition range of the data set. Values of \underline{K}' obtained during each cycle were then averaged to give the best estimate of \underline{K}' for the experiment. A sample of the output obtained during a fitting cycle with the Fortran IV computer program written for this purpose is shown in Table B-I.

Table B-I. Example of a fitting cycle for determination of K' from Eq. (B-1).

$\underline{\mathbf{E}_{i}} - \underline{\mathbf{E}_{j}}$ (V)		P(V)	N

VIII. Glossary:

- activity of component i, Eqs. (5) and (6).
- E cell potential (V).
- E_i cell potential (V), acid melt in compartment 2, Eq. (2).
- $\underline{\underline{\mathbf{E}}}_{\mathbf{i}}$ cell potential (V), basic melt in compartment 2, Eq. (2).
- K' stoichiometric equilibrium constant, Eq. (1).
- N mole fraction of AlCl3.
- \underline{N}_i mole fraction of AlCl₃ in acidic melt.
- N_i mole fraction of AlCl₃ in basic melt.
- \underline{N}_1 mole fraction of A1Cl₃ in compartment 1, Eq. (2).
- \underline{N}_{2} mole fraction of AlCl₃ in compartment 2, Eq. (2).
- ti transport number.
- X_i mole fraction.
- $\underline{\Psi}_{\mathbf{g}}$ cumulative weight of MEIC added (g).
- $\underline{\underline{W}}_{g}^{i}$ initial weight of MEIC in melt (g).
- μ₁ chemical potential.
